Resampling in silico:

Simulations with 20 replicates were constructed by subsampling (without replacement) from the R4IDs-sequencing and festival-resequenced data sets. For each simulation replicate, the R4ID input and resequencing run were subsampled randomly for 100, 500, 1000, 5000 and 10000 reads, in combination (25 orthogonal combinations per input sample). Each R4IDs dataset was converted to a BLASTN database separately.

Sample ID via BLASTN:

Each simulated sample was matched to every BLASTN database in turn with the following parameters: blastn -outfmt "6 sacc qacc length pident evalue" -evalue 0.01 -num_threads 6 -num_alignments 1 -max_hsps 1 -db \$this_db -query \$this_test_input

Only the top hit for each read is reported in the output file. Output files for each database/sample intensity combination (5 samples * 5 databases * 5 sampling intensities * 5 database intensities; 625 total) were then combined as follows: For each input sample at a given sampling/DB intensity combination, all hits against each of the 5 databases were collected for every read. The following ID statistics were then compiled:

Stat	Definition
TP	Reads only
one-	matching the
way	correct DB
FP one-	Reads only
way	matching an
	incorrect DB
TP	Reads
two-	matching the
way	correct DB,
	and at least
	one other DB,
	but with the
	longest number
	of identities for
	the correct DB
FP two-	Reads
way	matching the
	correct DB,
	and at least
	one other DB,
	but with the
	longest number
	of identities for
	the INcorrect
	DB; or
	matching more
	than one DB
	but NOT the
	correct one at
	all

Stat	Definition
mean	Average of (TP
bias	hit -
	next-best-hit)
	for all reads
	with at least
	two hits, one
	of which is for
	the correct DB
two-	Ratio of TP
way	two-way: total
rate	two-way hits
two-	Ratio of hits
way	with bias $>$
rate	50bp: total
with	two-way hits
cutoff	(e.g., more
	$\mathbf{stringent})$
total	Total number
hits	of reads with
	any hit to any
	DB

Not all replicate / sample combinations generated results owing to random error. In the plots below data were aggregated amongst replicates. 20 replicates were carried out in total.

 $\it Note$: For these the following sample identities were assumed...

levelplot((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP) ~ log10(sample_DB_intensity)*log10(spec

Silene uniflora

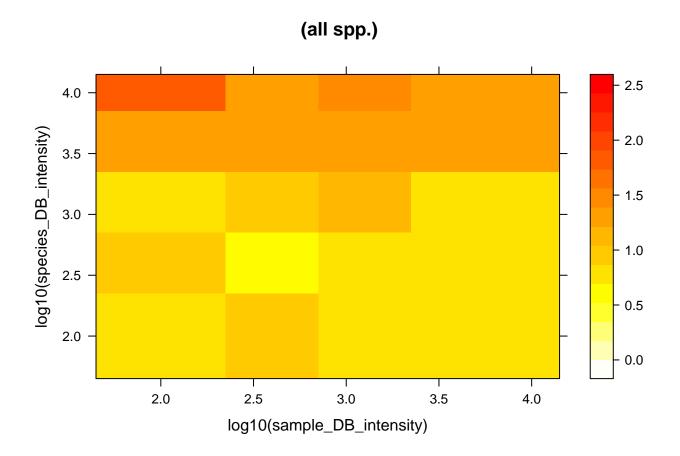

levelplot((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP) ~ log10(sample_DB_intensity)*log10(spec

Sorbus aria

levelplot((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP) ~ log10(sample_DB_intensity)*log10(spec

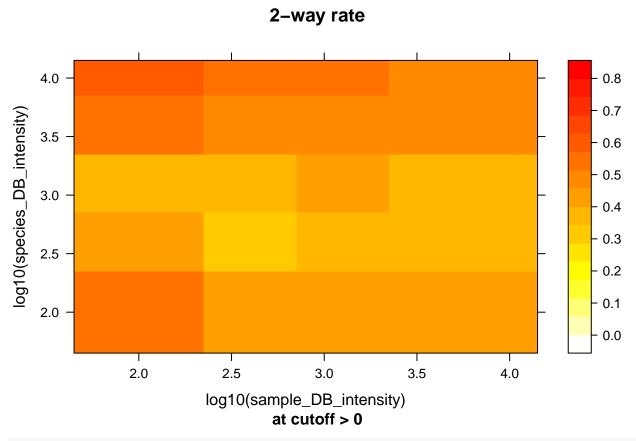

So far...

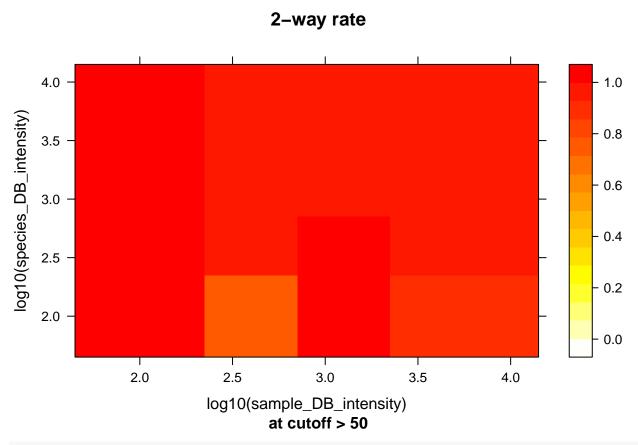

OK: something a bit odd is going on here, but basically it looks like a) it's all working OK more or less b) species DB intensity seems to make a bigger difference than sample effort/intensity..

To show this, collect all the aggregates in one:

```
par(mfrow=c(2,3))
levelplot(two_way_rate ~ log10(sample_DB_intensity)*log10(species_DB_intensity),data=all_reps, col.regi
```

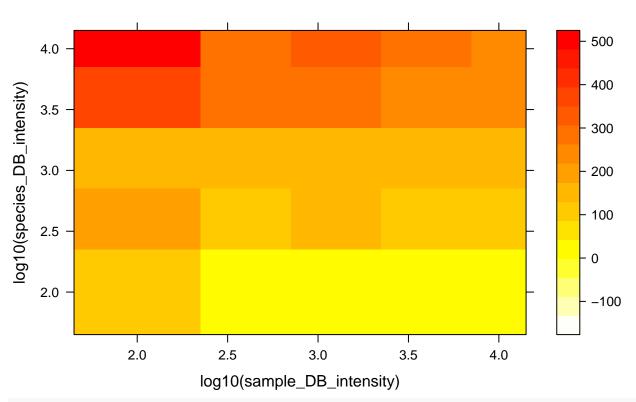

levelplot(two_way_rate_with_cutoff ~ log10(sample_DB_intensity)*log10(species_DB_intensity),data=all_re

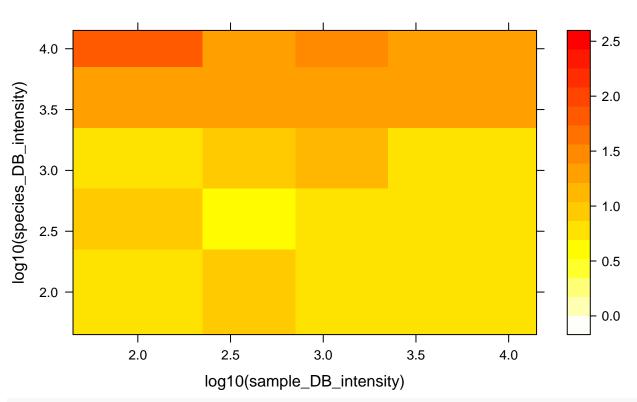

levelplot(mean_bias ~ log10(sample_DB_intensity)*log10(species_DB_intensity),data=all_reps, col.regions

mean #ident bias

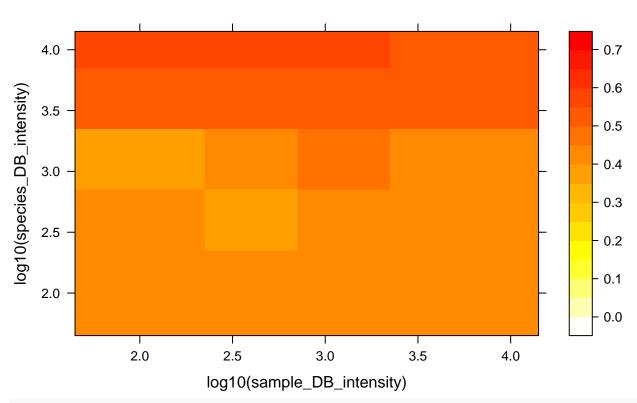

levelplot((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP) ~ log10(sample_DB_intensity)*log10(spec

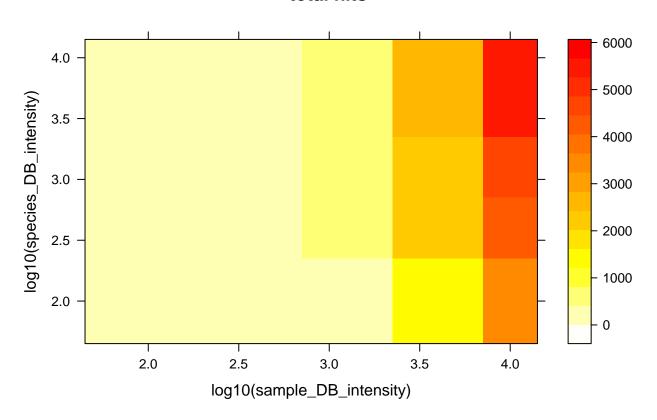

levelplot((one_way_TP + two_way_TP) / total_hits ~ log10(sample_DB_intensity)*log10(species_DB_intensity)

total TP:all_hits

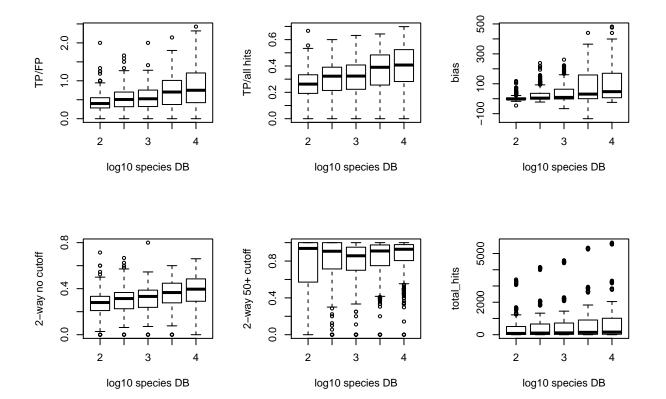

levelplot(total_hits ~ log10(sample_DB_intensity)*log10(species_DB_intensity),data=all_reps, col.region

total hits

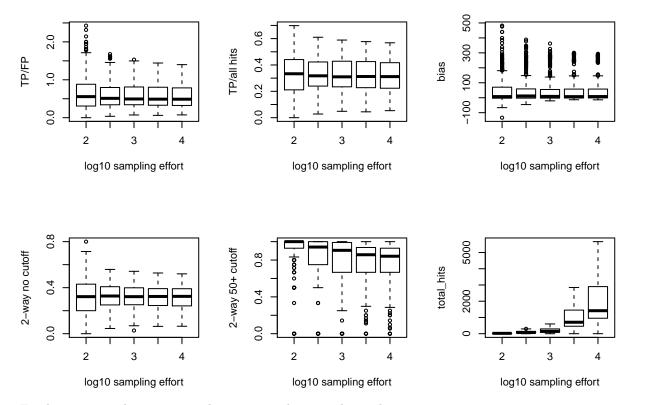

checking headline stuff; how does blast DB intensity affect outputs?:

```
par(mfrow=c(2,3))
boxplot((one_way_TP + two_way_TP) /(one_way_FP + two_way_FP) ~ log10(species_DB_intensity),data=all_rep
boxplot((one_way_TP + two_way_TP) /(total_hits) ~ log10(species_DB_intensity),data=all_reps, col.region
boxplot(mean_bias ~ log10(species_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(he
boxplot(two_way_rate ~ log10(species_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length
boxplot(two_way_rate_with_cutoff ~ log10(species_DB_intensity),data=all_reps, col.regions = heat.colors
boxplot(total_hits ~ log10(species_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(heat.colors)]
```

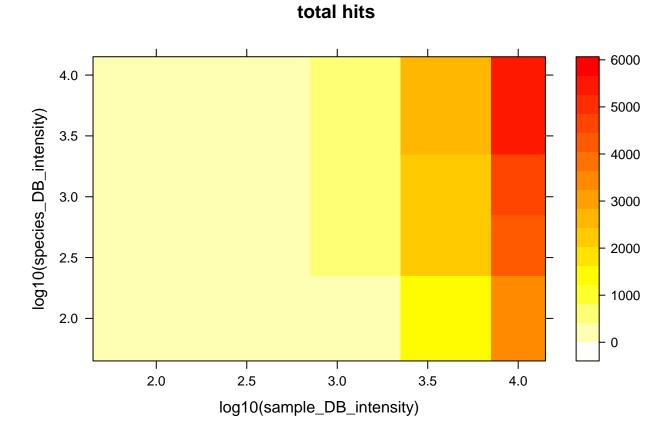

how does resequencing (sampling) intensity affect the same?:

```
par(mfrow=c(2,3))
boxplot((one_way_TP + two_way_TP) /(one_way_FP + two_way_FP) ~ log10(sample_DB_intensity),data=all_reps
boxplot((one_way_TP + two_way_TP) /(total_hits) ~ log10(sample_DB_intensity),data=all_reps, col.regions
boxplot(mean_bias ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(heaboxplot(two_way_rate ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(boxplot(two_way_rate_with_cutoff ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(boxplot(total_hits ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(heaboxplot(total_hits ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(heaboxplot(total_hits ~ log10(sample_DB_intensity),data=all_reps, col.regions = heat.colors(100)[length(heaboxplot(total_hits) ~ log10(sample_DB_i
```

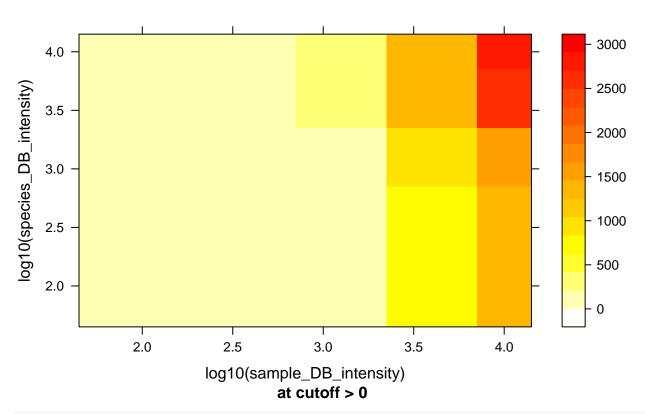

Final summary; ploting expected positive reads vs total sampling intensity:

levelplot(total_hits ~ log10(sample_DB_intensity)*log10(species_DB_intensity),data=all_reps, col.regions

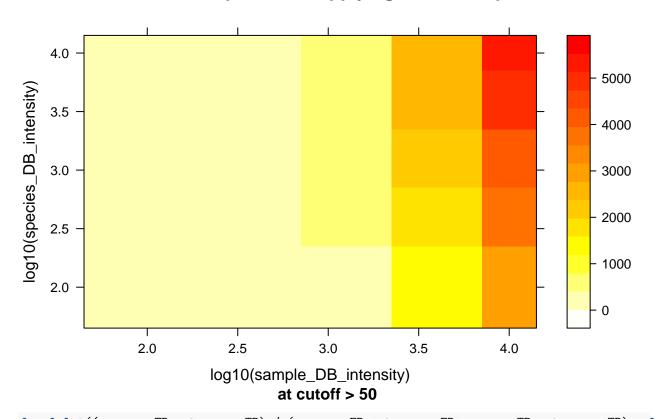

true positive hits expectation

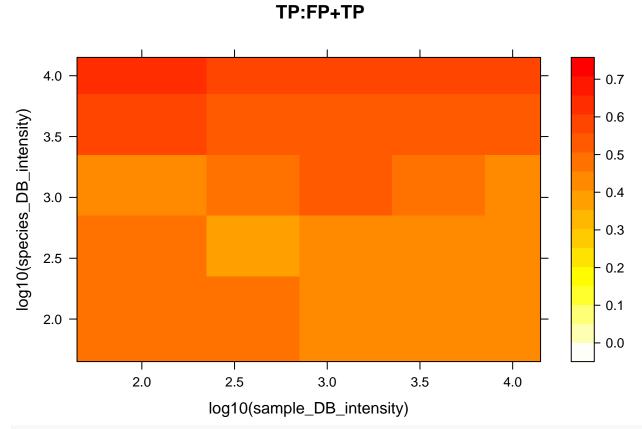

levelplot(two_way_rate_with_cutoff*total_hits ~ log10(sample_DB_intensity)*log10(species_DB_intensity),

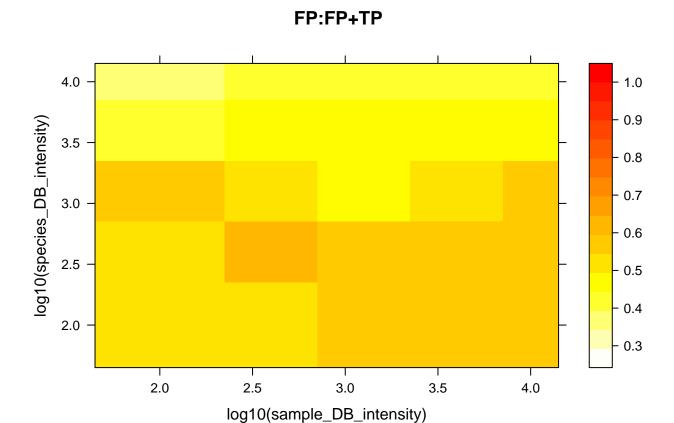

TP hit expectation, applying cutoff>50bp

levelplot((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP+one_way_TP + two_way_TP) ~ log10(sample_

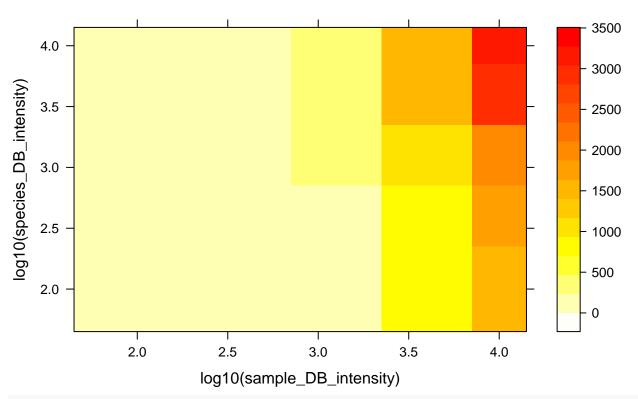

levelplot((one_way_FP + two_way_FP) / (one_way_FP + two_way_FP+one_way_TP + two_way_TP) ~ log10(sample_

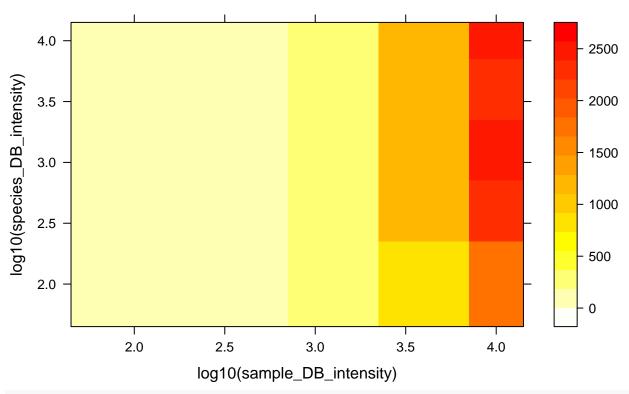

levelplot(((one_way_TP + two_way_TP) / (one_way_FP + two_way_FP+one_way_TP + two_way_TP)*total_hits) ~

expected reads TP:FP+TP

levelplot(((one_way_FP + two_way_FP) / (one_way_FP + two_way_FP+one_way_TP + two_way_TP)*total_hits) ~

expected reads FP:FP+TP

 $\#levelplot((one_way_TP \ + \ two_way_TP) \ / \ total_hits \ ~ log10(sample_DB_intensity) * log10(species_DB_intensity) + log$

Conclusion

Overall it seems to be working fine, e.g. we get hits and length differences that tend to correct at low intensities (10E4 is a bloody small amount of sequencing..!)

The biggest determinant of overall success seems to be R4IDs database sampling effort, not resequencing effort. This is interesting.

The length bias cutoff (hits' length difference greater than 50 in favour of TP database for a positive hit) seems to greatly improve accuracy at the expense of total number of hits. An optimal tradeoff will depend on the expected taxonomic distance between likely ID candidates.

Unsure what is driving the between-species differences, but the quality of the runs in terms of total yield and also q-scores is probably to blame, as well as genome size (since this affects coverage). Our target genomes here range from ~ 0.28 to 3.0Gbp, and our maximum R4IDs sequencing yields are in the 20Mbp (0.02Gbp) to 70Mbp zone; so we are sequencing much less than a 1x-coverage genome. Insofar as this works at all it is probably partly (largely?) due to bias; in the **A. thaliana** data we observed that plastid depths were ~ 350 x even though total genome depth $\sim 2x$ (max).

Note will need to know genome sizes more accurately if at all possible - only have C-values.
